NAME

```
archive_clear_error, archive_compression, archive_compression_name, archive_copy_error, archive_erron, archive_error_string, archive_format, archive format name, archive set error — libarchive utility functions
```

SYNOPSIS

```
#include <archive.h>
archive clear error(struct archive *);
int
archive_compression(struct archive *);
const char *
archive_compression_name(struct archive *);
archive_copy_error(struct archive *, struct archive *);
int
archive_errno(struct archive *);
const char *
archive_error_string(struct archive *);
int
archive format(struct archive *);
const char *
archive_format_name(struct archive *);
archive_set_error(struct archive *, int error_code, const char *fmt, . . . );
```

DESCRIPTION

These functions provide access to various information about the struct archive object used in the libarchive(3) library.

```
archive_clear_error()
```

Clears any error information left over from a previous call. Not generally used in client code.

archive_compression()

Returns a numeric code indicating the current compression. This value is set by archive_read_open().

```
archive_compression_name()
```

Returns a text description of the current compression suitable for display.

```
archive_copy_error()
```

Copies error information from one archive to another.

archive_errno()

Returns a numeric error code (see errno(2)) indicating the reason for the most recent error return.

archive_error_string()

Returns a textual error message suitable for display. The error message here is usually more specific than that obtained from passing the result of **archive_errno()** to strerror(3).

archive_format()

Returns a numeric code indicating the format of the current archive entry. This value is set by a successful call to **archive_read_next_header**(). Note that it is common for this value to

change from entry to entry. For example, a tar archive might have several entries that utilize GNU tar extensions and several entries that do not. These entries will have different format codes.

archive format name()

A textual description of the format of the current entry.

archive_set_error()

Sets the numeric error code and error description that will be returned by **archive_erro**() and **archive_error_string**(). This function should be used within I/O callbacks to set system-specific error codes and error descriptions. This function accepts a printf-like format string and arguments. However, you should be careful to use only the following printf format specifiers: "%c", "%d", "%jd", "%jo", "%ju", "%jx", "%ld", "%lo", "%lu", "%lx", "%o", "%u", "%s", "%x", "%%". Field-width specifiers and other printf features are not uniformly supported and should not be used.
